SUPPLEMENTARY STUDIES ON ANT LARVAE:
CERAPACHYINAE, PSEUDOMYRMECINAE
AND MYRMICINAE*

BY GEORGE C. WHEELER AND JEANETTE WHEELER
Laboratory of Desert Biology, Desert Research Institute,
University of Nevada System, Reno 89507

Subsequent to the publication of our first supplement on the ant
larvae of the subfamily Cerapachyinae (1964), our first paper on
Pseudomyrmecinae (1956) and several supplements on Myrmiciniae
(1960, 1972, 1973) we have received from other myrmecologists so
much additional material that it has now become necessary to pub-
lish a supplement.

Genus Phyracaces Emery

REVISION: The last sentence of our generic characterization
(1964: 69) should read: Hypopharynx usually spinulose dorsally.

Phyracaces elegans Wheeler (Fig. 2). Length (through spiracles)
about 4.7 mm. Very similar to Ph. larvatus (1964: 69) except as
follows. Body more slender. A pair of bosses on lateral surfaces of
venter of AI-AVI. Spiracles small, AI largest, diameter decreasing
posteriorly. Integument densely spinulose, spinules in short to long,
subtransverse to arcuate rows. Body hairs less numerous and shorter
(0.025-0.05 mm long). Head hairs shorter (0.009-0.019 mm long).
Posterior surface of labrum with a ventrally directed medial boss
bearing 6 sensilla, about 5 sensilla on each lateral surface. Mandi-
bles with narrower base. No spinules seen on hypopharynx.

YOUNG LARVA: Length (through spiracles) about 2.1 mm. Simi-
lar to mature larva above except as follows. Neck curved, abdomen
with straight ventral profile and C-shaped dorsal profile. Body hairs
shorter (0.01-0.033 mm long). Integument spinulose, spinules mi-
ute, isolated laterally and in short rows dorsally and ventrally.
Antennae less distinct. Maxillae lacking spinules; galea a slightly
raised pair of sensilla. No spinules seen on labium; opening of
sericteries a short slit.

VERY YOUNG LARVA: Length (through spiracles) about 1.5 mm.
Entire body arcuate ventrally. Otherwise similar to young larva.

Material studied: numerous larvae from New South Wales,
courtesy of Rev. B. B. Lowery.

*Manuscript received by the editor September 28, 1973

204
Fig. 1. Cerapachys (Sycia) australis: a, head in anterior view, ×95; b, left mandible in anterior view, ×314; c, larva in side view, ×22; d and e, two types of body hairs, ×444. Fig. 2. Phyracaces elegans: head in anterior view, ×74. Fig. 3. Tetraponera natalensis: left antenna in lateral view, ×339.

Phyracaces ficosus Wheeler. Length (through spiracles) about 4.4 mm. Very similar to Ph. larvatus (1964: 69) except in the following details. Spiracles on first abdominal somite slightly larger, remainder small and subequal. Body hairs shorter (0.013-0.063 mm long). Antennae with 2 sensilla each. Head hairs shorter (0.008-0.025 mm long). Galeae digitiform. (Material studied: 14 larvae from New South Wales, courtesy of Rev. B. B. Lowery.)

Genus Cerapachys F. Smith

Revision: Our generic characterization (1964: 67) should be replaced with the following: Leg vestiges small paraboloidal papillae. Body hairs usually simple. Head (including mouth parts) subpyriform in anterior view. Head hairs usually short. Mandibles long, slender and with median border erose. Maxillary palp short; galea long and digitiform.

Cerapachys (Sycia) australis Forel (Fig. 1). Length (through spiracles) about 3.2 mm. Body long and subcylindrical; about 12
differentiated somites; head on anterior end; a small posteriorly projecting boss on AX. Anus ventral. Spiracles small. Entire integument densely spinulose, spinules minute and in short to long straight or arcuate rows. Body hairs short, uniformly distributed and moderately numerous. Of two types: (1) 0.025-0.063 mm long, mostly bifid, sometimes with one or both branches rebranched, on all somites; (2) 0.037-0.05 mm long, simple, a few on each somite. Cranium subhexagonal in anterior view, slightly longer than wide. Antennae large, each a low mound with 3 minute sensilla, each bearing a minute spinule. Head hairs few, 0.025-0.05 mm long, simple or bifid. Labrum subarcuate, about twice as wide as long; anterior surface with 8 sensilla on and near ventral border; posterior surface with about 6 sensilla ventromedially and with a few oblique arcuate rows of minute spinules. Mandibles narrowly subtriangular in anterior view; apex rather long, narrow and heavily sclerotized; medial border with 6-8 small denticles. Maxillae with apex paraboloidal and sparsely spinulose, spinules minute to short and in a few arcuate rows; palp a peg with 4 (2 encapsulated and 2 bearing a spinule each) apical and one lateral sensilla; galea digitiform with 2 apical sensilla, each bearing a minute spinule. Labium subtrapezoidal, widest distally, anterior surface densely spinulose, spinules minute and in numerous short arcuate rows; palp a rounded elevation with 5 (2 encapsulated and 3 bearing a spinule each) sensilla; an isolated sensillum between each palp and opening of sericteries; the latter a slit in a shallow depression on anterior surface. Hypopharynx with minute spinules in long transverse sub-parallel rows. (Material studied: 10 larvae from Queensland, courtesy of Rev. B. B. Lowery.)

**Subfamily Pseudomyrmecinae**

We have never been able to key the genera of this subfamily. Except for head shape, where the difference in the species of *Pachysimma* is greater than that between any two genera, some of the variants of any character in any genus can be found in other genera.

Bernard (1951: 1053) included larval characters in his characterization of the subfamily, which he called family Promyrmicidae.

Sudd (1967: 123) discussed the feeding of the larvae. He stated (erroneously) that the trophothylax was formed by the bases of the rudimentary legs; we have shown (1956: 375, 383) that it is “formed from the depressed ventral surface of the thorax and elaboration of the first and second abdominal somites.”
Genus *Pseudomyrmex* Lund

Janzen (1967: 344). Beltian bodies are cut up by the workers and fed to the larvae.

The following species of *Pseudomyrmex* are compared with *Ps. alliodorae* 1956: 379); only differences are given here.

*Pseudomyrmex adustus* Borgmeier. Length (through spiracles) about 4.8 mm; straight length about 4.6 mm. Body hairs: (2) 0.05-0.25 mm long, longest of AI-AV; (3) 0.2-0.25 mm long, 2 only on each Ti-3 and AI-AIII. Head hairs more numerous and 0.05-0.25 mm long. Posterior surface of labrum with a cluster of 3 sensilla in the middle of each half. (Material studied: 7 larvae from Brazil, courtesy of Dr. K. Lenko.)

*Pseudomyrmex elongatus* Borgmeier. Length (through spiracles) about 3.8 mm; straight length about 3.6 mm. Body hairs longer: (1) 0.006-0.018 mm long; (2) 0.018-0.2 mm long; (3) 0.175-0.22 mm long, 4 in a row across the dorsum of each Ti-3 and AI-AIV. Head hairs more numerous and slightly longer (0.01-0.05 mm long). (Material studied: 15 larvae from Brazil, courtesy of Dr. K. Lenko.)

*Pseudomyrmex schuppi* Forel. Length (through spiracles) about 5.9 mm; straight length about 5.7 mm. Largest spiracles on AI. Body hairs longer: (1) 0.013-0.025 mm long; (2) 0.038-0.25 mm long; (3) 0.25-0.33 mm long, 4 in a row across the dorsum of each Ti-3 and AI-AIII. (Material studied: numerous larvae from Brazil, courtesy of Dr. K. Lenko.)

*Pseudomyrmex subtilissimus* Emery. Length (through spiracles) about 4.3 mm; straight length about 3.9 mm. Body hairs longer: (1) 0.006-0.018 mm long; (2) 0.018-0.15 mm long; (3) 0.15 mm long, 4 in a row across the dorsum of each Ti-3 and AI-AIV. Head hairs slightly longer (0.025-0.05 mm long). (Material studied: 6 larvae from Brazil, courtesy of Dr. K. Lenko.)

*Pseudomyrmex termitarius* F. Smith. Length (through spiracles) about 5.1 mm; straight length about 4.7 mm. Body stouter. Body hairs about twice as numerous: (1) 0.013-0.05 mm long; (2) 0.05-0.275 mm long; (3) 0.25-0.35 mm long, 4 in a row across dorsum of each Ti-3 and AI-AIV. Head hairs more numerous, longer (0.013-0.05 mm long) and finely denticulate. Labrum with width twice the length, with anterior lobes more prominent and with 2
minute hairs on anterior surface. Mandibles with teeth stouter and blunter; lateral outline less curved; denticles on anterior surface more numerous. Maxillary apex less constricted and with spinules longer and covering a greater portion of the surface. Labium with more numerous spinules. (Material studied: 9 larvae from Brazil, courtesy of Dr. K. Lenko.)

Genus Tetraponera F. Smith

_Tetraponera natalensis_ F. Smith (Fig. 3). Length (through spiracles) about 8.2 mm; straight length about 6.2 mm. Similar to _T. aitkeni_ (1956: 388) except as follows. Body slightly stouter at AV and AVI. Integument of AIX and AX with minute spinules. Body hairs: (1) 0.008-0.075 mm long; (2) 0.025-0.15 mm long, longest with tip branched or denticulate; (3) 0.175-0.3 mm long, 4 in a row across the dorsum of each T1-3 and AI-AVI. Each antenna represented by 3 individually raised sensilla on a small base. Head hairs longer (0.013-0.11 mm long) and less numerous, with or without alveolus and articular membrane, some with denticles near the tip. Labrum with breadth less than twice length; borders sinuate; anterior surface with 6 sensilla and 2 hairs on each half; posterior surface with 9 sensilla on each half; spinules as in _T. aitkeni_. Anteromedial surface of mandibles with large spinules, which are isolated or in short rows of 2 or 3. Maxillae with rather numerous long spinules in short arcuate rows; palp represented by a cluster of 5 sensilla on a slight elevation. (Material studied: numerous larvae from South Africa, courtesy of Dr. W. L. Brown.)

Genus Pachysima Emery

_Pachysima latifrons_ Emery: Bernard (1951: 1054-1057) described and figured the young (after W. M. Wheeler).

Genus Viticicola Wheeler

_Viticicola tessmanni_ (Stitz): Bernard (1951: 1054) described and figured the larva (after W. M. Wheeler).

Subfamily Myrmicinae

Ettershank (1966: 161, 162): “The larvae of the Formicidae have not been used to any extent in taxonomic studies, although numerous descriptions and figures of scattered genera and species occur in the literature. The only wide-scale comparative larval study
that has been attempted is the series of papers by G. C. Wheeler (later with J. Wheeler), which constitute a fundamental contribution to the subject that will be used for a long time." "Reference to all the publications by the Wheelers on myrmicine ants are contained in a summary article (G. C. and J. Wheeler 1960). In this paper, the authors conclude that three characters are of major importance: body profile, mandible shape, and setal form. They recognize 22 body profiles and 30 mandibular shape categories all of which are explained and illustrated."

**Genus Messor Forel**

*Messor capitatus* Latreille: Delage (1968a) gave in a table the sizes and abundance of larvae throughout the year. She stated that only small larvae overwinter. She (1968b) discussed larval enzymes and digestion.

**Genus Pheidole Westwood**

Kempf (1972: 457): *Ph. vallifica* is the host of the eucharitid *Orasema costaricensis* Wheeler and Wheeler.

**Genus Melissotarsus Emery**

Delage-Darchen (1972a): Hairs few, long, with bifid tips. Crude sketch of a larva on p. 219.

**Genus Crematogaster Lund**

Delage-Darchen (1972b) found only three larval stages in *C. (Nematocrema) stadelmanni* Mayr. Fig. 1 hairs enlarged; Fig. 2 and 3 larvae of various stages in side view; Fig. 4 head in anterior view. Pilosity is taxonomically worthless because of extreme variation between colonies and even in the same colony.

**Genus Monomorium Mayr**

Cloudsley-Thompson (1962: 179): The calliphorid flies *Bengalia peuhi* Vil. and *B. minor* Malloch fed on the larvae of *M. salomonis* (Linnaeus) in the central Sudan.

Van Pelt and Van Pelt (1972: 978): Larvae of the syrphid *Microdon baliopterus* Loew fed upon the larvae of *M. minimum* (Buckley).
Genus **Solenopsis** Westwood

Markin et al. (1972: 1053): Life cycle of *Solenopsis invicta* Buren in an incipient colony: egg 6-8 days, larva 14-15 days, pupa 20-24 days.

Genus **Tetramorium** Mayr

*Tetramorium caespitum* (Linnaeus). Donisthorpe (1927: 197): “The larvae were fed with disgorged liquid food as long as they were young and gathered together in groups, but when they grew older and were separated, the workers fed them with solid substances.” Many larvae were hung on to the plaster walls of the nest by their anchor-tipped hairs.
